ABSTRACT

In this work, the azoxytriazolone (AZTO) was synthesized by electrochemical reduction 5-nitro-1,2,4-triazol-3-one (NTO) under different types of electrolytes which were Na_2SO_4 and H_2SO_4 . By comparing the yield of AZTO/azoTO synthesized under different electrolyte conditions, the work found that sulfuric acid as the electrolyte has a positive effect on the synthesis of AZTO. On this basis, the high-concentration AZTO was prepared by regulating the concentrations of sulfuric acid (0.05M, 0.1M, 0.5M, 1M). Finally, by introducing an appropriate amount of NaOH, we successfully achieved the separation and purification of AZTO from the mixture of AZTO and azoTO. In addition, single crystal AZTO was also prepared in this experiment to test its crystal structure, which illustrated that the crystal density of AZTO is 1.902 g/cm^3 at 193 K, belonging to the monoclinic crystal system with space group $\text{P2}_1/n$. The thermal properties results of AZTO showed that the thermal stability properties of AZTO were affected by AZTO/azoTO ratio, and the thermal decomposition peak of pure AZTO is 352°C when the content of azoTO is zero. On the contrary, the BAM susceptibility tester test demonstrated the impact susceptibility is 30 J and the friction susceptibility is greater than 360 N of AZTO, which are unaffected on azoTO. According to the K-J empirical formula, the blasting velocity and detonation pressure of AZTO were 7713.5 m/s and 26.1 GPa, respectively. The influences of different types of electrolytes and sulfuric acid concentrations on the yield of AZTO were evaluated, and the relevant reaction mechanism of electrochemical synthesis of AZTO and azoTO was supplemented in this paper.

1. Introduction

With the continuous expansion of the application scope of energetic materials, more and more attention has been paid to the environmental impact of the synthesis and application of energetic materials. At the same time, more and more research has also focused on the development of green synthetic methods and treatment of manufacturing waste, as well as the design and synthesis of safer and more environmentally friendly energy materials [1–6]. Among many compounds, nitrogen-rich compounds have high-energy N–N and C–N bonds, and their decomposition products are mainly friendly N_2 , which is environmentally friendly. Therefore, it is an ideal energetic material. Compared with traditional energetic materials, high nitrogen compounds have the characteristics of high formation enthalpy and good stability, and the carbon monoxide and dust produced during combustion are less than other organic explosives due to their higher nitrogen content [7] #66; [8] #68. However, the synthesis of these high-nitrogen compounds is facing unprecedented challenges. In the synthesis of high nitrogen compounds, strong oxidants or reducing agents such as potassium permanganate, hydrazine

hydrate, and hydrogen peroxide are needed [9] #70; [10] #71. And for some heterocyclic energetic materials containing nitrogen, their synthesis sometimes requires the use of toxic or heavy metal catalysts [11] #75. In view of this, an electrochemical synthesis method is proposed to solve these problems. Electrochemical synthesis refers to the use of electrons as oxidants or reducing agents without additional oxidant or reducing agents for reaction without adding other additives, which decreases the cost of materials synthesis and waste treatment, and reduces the difficulty of product separation and purification. The method has mild reaction conditions and does not require additional heating equipment [12] #76; [13] #77; [14] #78. A number of related studies have been reported, for example, Longrui Chen et al. constructed a flow device to achieve the synthesis of 100 g quantities of cyclobutane by electrochemical oxidation [15] #49; Huichao He et al. designed and synthesised W and Mo co-doped BiVO_4 thin film electrodes and synthesised azotetrazoles by electrochemical methods of oxidative dehydrogenation coupling under room temperature light conditions [16] #79; wastewater treatment by electrochemical methods was also subjected to great interest. NTO (5-nitro-1,2,4-triazol-3-one) is a blunt high-energy den-

sity compound that is difficult to treat by conventional methods such as adsorption carbon scrubbers due to its high water solubility (1.28 g/100 mL at 19 °C) {[17] #80; [18] #81}. Wallace et al. proposed affordable remediation of wastewater by electrochemical methods, requiring only electrical input, no other additional chemical loading, and giving access to the insensitive energetic compound azoxytriazolone (AZTO) of some value, which can be obtained by direct filtration with low recovery costs due to the low solubility of AZTO in water {[19] #82}. However, AZTO is highly susceptible to further reduction to azotriazolone (azoTO) and the relatively similar nature of the two makes it difficult to purify by column chromatography and recrystallisation, thus making it impossible to obtain pure AZTO, which limits its further application {[20] #83}.

In this work, the influence of electrolyte type on the synthesis of AZTO and azoTO was studied and obtained better reaction conditions for the preparation of high-yield AZTO by optimizing the electrolyte concentration. Then, AZTO and azoTO were separated and purified for the first time by salt formation reaction. Moreover, the purity, crystal structure, thermal stability, and mechanical sensitivity properties of AZTO prepared from this experiment were analyzed and compared by single crystal X-ray diffraction, infrared spectroscopy, nuclear magnetic resonance hydrogen spectroscopy, comprehensive thermal analysis (TGA-DSC), and elemental analysis. Finally, the detonation performance was predicted by K-J empirical formula.

2. Experiment section

2.1. Material and methods

General: Unless otherwise stated, all reagents and solvents were used as is (Aladdin). Thermogravimetric (TG) and differential scanning calorimetry (DSC) tests were carried out using the SDT Q160 produced by the TA instrument in the nitrogen atmosphere with a heating rate of 10 K/min in an alumina disc. ¹H NMR spectra were measured by the JEOLGSX-600, and all samples used for NMR hydrogen spectroscopy were dissolved in dimethyl sulfoxide (DMSO-d₆). Chemical shifts were expressed in ppm relative to TMS(1H) and all samples used for NMR hydrogen spectroscopy were dissolved in dimethyl sulfoxide (DMSO-d₆). The infrared spectra of the samples in the range of 400–4000 cm⁻¹ were recorded by the KBr tableting method using Nicolet 5700 Fourier transform infrared spectrometer (FT-IR). Elemental analysis (C, H, and N) was determined by the Vario EL CUBE-Elemental Analyzer. The crystal structure of AZTO was determined by single crystal X-ray diffraction. The data collection was performed on a Bruker APEX-II CCD X-ray diffractometer (Bruker Germany) with highly oriented graphite crystal monochromated GaK/α radiation (λ = 0.71073). The crystal was kept at 193K during data collection. Using Olex2 {[21] #85}, the structure was solved with the SHELXT {[22] #86} structure solution program using Intrinsic Phasing and refined with the SHELXL {[23] #87} refinement package using Least Squares minimisation. In this paper, all Cyclic Voltammetry (CV) tests and electrolysis experiments were performed in the CHI 760 electrochemical workstation (Shanghai, China). 3-Nitro-1,2,4-triazol-5-one (NTO) was synthesized according to the method reported in the literature {[24] #84}.

2.2. Syntheses of azoxytriazolone (AZTO)

The compound of AZTO was prepared according to the method reported by Wallace et al. {[25] #45}. 500 mg NTO was dissolved in 50 ml 0.1 mol/L H₂SO₄ aqueous solutions. In a single electrolysis chamber, a carbon working electrode, platinum counter electrode, and Ag/AgCl reference electrode were used for electrolysis at -1 V and 5 °C for 8 h. Then the mixture of AZTO and azoTO was obtained by filtration, and an appropriate amount of NaOH aqueous solution was added until AZTO was completely dissolved in water. The remaining azoTO was obtained by filtration drying with a yield of 10.2%. Subsequently, concentrated sulfuric acid was used to acidify the filtrate to produce a large amount of

yellow-green precipitate. AZTO was obtained by filtration and drying, and the yield was 51.2%.

Azoxotriazolone (AZTO) ¹H NMR (600MHz, DMSO-d₆, ppm) δ = 13.20 (s, 1H), 12.48 (s, 1H), 12.45 (s, 1H), 12.08 (s, 1H). ¹³C NMR (150Mz, DMSO-d₆, ppm) δ = 144.85, 146.40, 154.10, 154.48. EA: (C₄H₄N₈O₃, 212.1 g/mol) calcd: 22.65% C, 1.90% H, 52.82% N, found: 22.55% C, 2.3% H, 51.84% N; DSC (10 °C/min) T_{dec} at 352 °C. IR (cm⁻¹) ν = 3167.06, 3057.19, 2808.59, 1693.30, 1578.521534.32, 1442.86, 1133.50, 1013.81, 899.03, 810.03, 740. azotriazolone (azoTO) ¹H NMR (600 MHz, DMSO-d₆, ppm) δ = 12.74 (s, 1H), 12.44 (s, 1H). ¹³C NMR (150 Mz, DMSO-d₆, ppm) δ = 154.70, 154.76. EA: (C₄H₄N₈O₂, 196.1 g/mol) calcd: 24.50% C, 2.06% H, 57.13% N, found: 23.36% C, 2.16% H, 56.89%. IR (cm⁻¹) ν = 3142.5, 3054.7, 2950.9, 2831.3, 1682.8, 1540.4, 1468.6, 1426.9, 1286.9, 1118.8, 1040.8, 1018.1, 810.6, 745.6, 671.3, 482.9. BAM impact: > 40 J; BAM friction > 360 N.

3. Results and discussion

In order to understand the influence of sulfuric acid concentration on the yield of AZTO, NTO reduction experiments were carried out at different concentrations of sulfuric acid. Firstly, sulfuric acid with the concentration of 0.05 M, 0.1 M, 0.5 M, and 1 M H₂SO₄ was selected as the electrolyte, and the redox peaks of NTO (500 mg) at different concentrations were measured by cyclic voltammetry in this experiment. Fig. 1(a) shows the CV curve of NTO during electrolysis in H₂SO₄. It can be seen from Fig. 1(a) that, the reduction peaks of NTO shift to the direction of low potential as the increasing of electrolyte concentration, which indicates that NTO is more prone to secondary reduction and is not conducive to the synthesis of AZTO at high sulfuric acid concentration. In addition, the work quantitatively calculated the content of AZTO in the mixture of AZTO and azoTO by Hydrogen spectrum and obtained the relationship between the sulfuric acid concentration and the AZTO content. A mixture of AZTO and azoTO is obtained by washing the NTO electrolytic product. The total yield and AZTO percentage are listed in Table 1. It can be seen from Table 1 that as the electrolyte concentration decreases, the proportion and total yield of AZTO gradually increase. When the sulfuric acid concentration is 0.05 M, the proportion and total yield of AZTO reach the maximum, which are 67 % and 80 %, respectively. The above results indicate that the presence of acid may promote the further reduction reaction through proton-coupled electron transfer. Therefore, reducing the concentration of H₂SO₄ solution can inhibit the secondary reduction to some extent and improve the yield of AZTO {[26] #44}.

In the above analysis, we found that low-concentration sulfuric acid solution as the electrolyte is beneficial to the formation of AZTO. Therefore, Na₂SO₄ was selected as the electrolyte to explore the effect of a neutral electrolyte on the formation of AZTO. Fig. 1(b) is the CV curve of NTO electrolysis in Na₂SO₄ electrolyte. When the potential is -0.38 V, the two electrolytes have a reduction peak on the CV curve at the same position, which may be due to the same pH of the two solutions, which confirms the proton-coupled electron transfer effect. However, the other reduction peak was also observed at -0.83 V in the CV curve of 0.1 M Na₂SO₄. In the CV study of NTO, Na₂SO₄ was used as an electrolyte. From Fig. 1(b), it can be seen that both of them have a reduction peak at -0.38 V at the same time, which may be due to the same pH of the two solutions, which confirms the proton-coupled electron transfer effect. However, when 0.1 M Na₂SO₄ is used as the electrolyte, a second reduction peak appears at -0.83 V, which may be due to the fact that as the reaction proceeds, H⁺ is continuously consumed. The AZTO synthesized by the electrochemical reduction of NTO exists in the form of anions, which promotes the solubility of AZTO in water, resulting in the secondary reduction of AZTO and the formation of a reduction peak. In the experiment of NTO electrolysis in Na₂SO₄ solution, the color of the electrolyte was observed to change gradually from yellow-green to orange-red, which indicated that the pH value of the electrolyte system changed from acidic to alkaline, and no precipitates were produced in

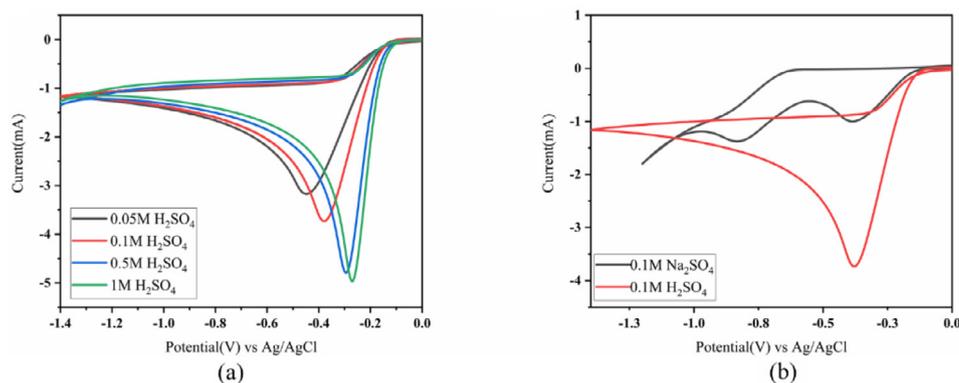

Fig. 1. (a) The CV of NTO in a 0.05 M, 0.1 M, 0.5 M, 1 M H_2SO_4 solution was accomplished using a 2 mm glassy carbon working electrode, a carbon plate counter electrode and an Ag/AgCl reference electrode at a rate of 0.1 V. (b) The CV of NTO in a 0.1 M H_2SO_4 and 0.1 M Na_2SO_4 solution was accomplished using a 2 mm glassy carbon working electrode, a carbon plate counter electrode and an Ag/AgCl reference electrode at a rate of 0.1 V.

2	5	0.1 M H_2SO_4	C/Pt	-1	63	80
3	5	0.5 M H_2SO_4	C/Pt	-1	55	64
4	5	1 M H_2SO_4	C/Pt	-1	50	56

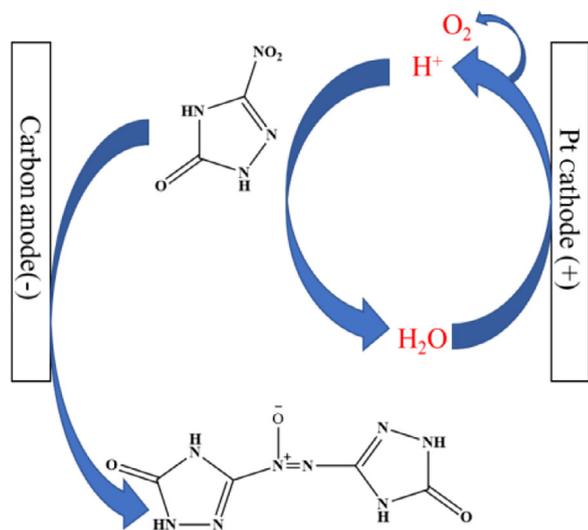

Fig. 2. A mechanism is proposed for the cathodic reduction of azo coupling of NTO to produce AZTO in acidic solutions.

the solution. However, a small amount of yellow precipitate was produced in the solution after acidification of the electrolyte with concentrated sulfuric acid, and the main component of that was identified by NMR hydrogen spectroscopy as azoTO. The experimental phenomena were consistent with the above analysis, which suggests the acidic electrolyte could avoid further reduction and increase the yield of AZTO by inhibiting the deprotonation of the triazole ring and reducing the solubility of AZTO in water. Based on the above results, the reaction mechanism of electrochemical reduction of NTO to AZTO is described in Fig. 2. By further optimizing the reaction conditions, it was found that the yield of AZTO could be further increased at low temperatures, and the experimental results were consistent with the literature reports. Attempts to further extend the electrolysis time found that part of AZTO was further reduced to azoTO, resulting in a decrease in the yield of AZTO.

3.1. Isolation and purification of AZTO and azoTO

AZTO and azoTO are insoluble in any solvent other than DMSO, such as methanol, ethanol, DMF, ethyl acetate, acetonitrile, etc. The solubility in water is also very low, so it cannot be separated and purified by column chromatography, and the DMSO/ H_2O liquid phase diffusion crystallization will lead to an increase in the proportion of azoTO. Due to the deprotonation of the triazole ring, AZTO and azoTO can be miscible with water by increasing their solubility in water through salt-forming reactions with alkali. Therefore, we made the mixture of AZTO and azoTO completely dissolved in water by adding an excess of base, recrystallized it in water, and then redissolved the obtained solid in water and acidified by sulfuric acid, in order to obtain high-purity AZTO. However, it was found that AZTO and azoTO were not separated by ^1H NMR spectroscopy, and the proportion of azoTO was further increased. In view of this, this work uses the structural differences between AZTO and azoTO to find a method to separate them. For AZTO, the N-O bond in its structure can absorb electrons, which can further reduce the electron cloud density and promote the proton dissociation of the triazole ring. Theoretically, the acidity of AZTO is higher than that of azoTO, and it preferentially reacts with alkali to form salts. Therefore, it is only necessary to control the amount of alkali to make AZTO react completely, and through the difference in solubility between AZTO and azoTO to achieve separation and purification. To verify this conjecture, the mixture of AZTO and azoTO was dispersed in the appropriate amount of NaOH solution and stirred for 5 min to filter out the yellow precipitate. Then the pH of the filtrate was adjusted to 2 with concentrated sulfuric acid, and the yellow-green precipitate was obtained by filtration and drying. The two precipitates were tested by multinuclear NMR (^1H , ^{13}C). From Figs. 3 and 5, it can be seen that the ^1H NMR characteristic peaks of AZTO are 13.20 ppm, 12.48 ppm, 12.44 ppm and 12.08 ppm, and the ^{13}C NMR characteristic peaks are 144.85 ppm, 146.40 ppm, 154.10 ppm, 154.48 ppm, and no related peaks of azoTO are observed. From Figs. 4 and 6, it can be seen that the ^1H NMR characteristic peak of azoTO is 12.74 ppm, 12.44 ppm, and the ^{13}C NMR characteristic peak is 154.70 ppm, 154.76 ppm. The results show that, compared with azoTO, AZTO preferentially undergoes a salt-forming reaction with alkali. Taking advantage of this property, the separation and purification of AZTO and azoTO were successfully achieved.

3.2. Single crystal X-ray structure determinations

The AZTO crystal data and structural parameters are shown in Table 3, and the molecular structure diagram, hydrogen bond network diagram, and cell stacking diagram are shown in Figs. 7 and 8. The bond length information is listed in Table 4, the bond angle information is listed in Table 5, and the hydrogen bond information is listed in Table 6.

The crystal data for AZTO show that it belongs to the monoclinic system, P2₁/n space group, with cell parameters of $a = 6.5061(3)$ Å, $b = 5.0081(3)$ Å, $c = 11.4206(7)$ Å, $\alpha = 90^\circ$, $\beta = 95.372(2)^\circ$, $\gamma = 90^\circ$, $Z = 2$ and a crystal density of 1.902 g/cm³ measured at 193 K. From Fig. 5 it is clear that there is a disorder in the AZTO molecule and the O atom is found to be disordered, which is caused by the whole AZTO molecule being flipped by 180° [27] #96}.

As displayed in Table 4, the bond length of N(2)-N(3) on the triazole ring is 1.363 Å, the N=N bond length connecting the triazole ring is 1.275 Å, both between the N-N single bond length (1.454 Å) and the

of detonation (kcal/g) and the loaded density of explosives (g/cm³). The measured single crystal density was used for the calculation here.

From Table 7, AZTO detonation speed of 7713.5 m/s, detonation pressure of 26.1 GPa, azoTO detonation speed of 7459.3 m/s, detonation pressure of 23.8 GPa, the detonation performance of both better than TNT (6881 m/s, 19.5 GPa). AZTO and azoTO show good thermal stability, both with thermal onset decomposition temperatures > 300 °C, and are more stable than RDX and TNT {[34] #95}.

4. Conclusions

In summary, this work successfully obtained a method for the separation and purification of AZTO and azoTO by using the difference in properties of AZTO and azoTO. The reaction conditions were further optimized and the related reaction mechanism was supplemented. In

addition, AZTO Single crystal prepared by liquid-phase diffusion was tested to master the crystal structure. AZTO belongs to the monoclinic crystal system, with the space group of $P2_1/n$, and the crystal density at 193K is higher than that of other energetic materials, which is 1.902 g/cm³. The results of TGA-DSC show that the high-purity AZTO obtained in this paper has good thermal stability ($T_{dec} = 352$ °C), which is related to the abundant hydrogen bonding and Π - Π interaction between its molecules. According to the enthalpy of formation and crystal density obtained from the experiment, the detonation parameters of AZTO and azoTO were calculated by the K-J empirical formula. The results illustrate that the detonation pressure and detonation velocity of AZTO ($P = 26.1$ GPa, $D = 7713.5$ m/s) and azoTO ($P = 23.8$ GPa, $D = 7459.3$ m/s) are superior to TNT ($D = 6881$ m/s, $P = 19.5$ GPa). And the impact sensitivity and friction sensitivity of AZTO ($IS = 30$ J, $FS = 360$ N) are also lower than those of the traditional energy-containing materials TNT

Scheme 1. Synthetic applications.

and RDX. The above analysis displays that the high-purity energetic material AZTO can be obtained by the scheme described in this paper, and AZTO has good performance (Scheme 1, Table 2).
